1. Introduction

Trade liberalization

Trade liberalization is seen by many governments as a vehicle to poverty alleviation in Africa. Yet, recent empirical evidence suggests that while trade liberalization can facilitate poverty reduction, there can be no simple general conclusion about the relationship between trade liberalization and poverty (Winters et al., 2004; Reimer, 2002). Although trade liberalization seems to have contributed to poverty reduction in some countries in the world, it actually worsened poverty in others (Winters et al., 2004; Reimer, 2002). As such, it is difficult to generalize from one country’s experience to another, which suggests that we can only rely on country-specific evidence. This paper takes these concerns by examining the impact of trade liberalization on the incidence of poverty in Uganda.

Literature on trade liberalization and poverty is vast, but it leaves the question open as to whether multilateral liberalization can be more successful in reducing poverty than regional integration. One of the major arguments in favour of free trade is its potential for ‘trade creation’, associated with a shift in production in the direction of comparative advantage, which leads to saving resources and providing the consumer with cheap goods. This may not always be the case; free trade (especially regional integration) may also lead to trade diversion by allowing high-cost imports from partner countries to displace low-cost imports (cheaper goods) from outside the bloc. There is array of theoretical and empirical literature on these topics, which reinforces the earlier argument that it is difficult to generalize from one country’s experience to another.

Hertel et al. (2003) examine how multilateral trade liberalization affects poverty in each of the seven different developing countries. Their findings suggest that multilateral trade liberalization reduced overall poverty in Indonesia, Philippines, Uganda, and Zambia, but increased overall poverty in Brazil, Chile, and Thailand. From 16 case studies for Latin American countries documented by Ganuza et al. (2005), poverty fell in 12 of them. Poverty increased in Costa Rica, Ecuador, Paraguay and Venezuela amidst overall decline in prices of their agricultural exports during the same period.

In Asia, Cororaton (2003) observes that a complete removal of tariffs on imports reduced poverty in the Philippines, but increased income inequality. Similarly, Cororaton et al. (2005) findings suggest that tariff reductions in the Philippines between 1994 and 2000 were generally poverty-reducing, although the reduction in poverty was much higher in urban areas than in rural areas, where poverty is widespread. Cockburn (2001) reports
the distribution impact of trade policies in Nepal, suggesting that a complete removal of tariffs would reduce poverty in urban areas while increasing it in rural areas.

In Africa, Bautista et al. (1998) and Chitiga et al. (2005) find that trade liberalization reduced overall poverty in Zimbabwe, although poverty fell more in urban than in rural areas. In Morocco, Ravallion and Lokshin (1994) argue that small cuts in protection (in order of 10%) would increase household inequality in Morocco, as benefits of tariff cuts flow disproportionately to the wealthy.

In Uganda, there is no doubt that a lot of attention has been on poverty reduction. However, very few studies have attempted to explore the relationship between trade and poverty. Insightful examples such as Blake et al. (2002), and Hertel et al. (2003) have suggested that multilateral trade liberalization is likely to be pro-poor, especially through increase in factor incomes. However, since the GTAP database is designed for broad country average, the Hertel et al. (2003) findings need to be reinforced with Uganda-specific case study. Studies that offer comprehensive analysis of poverty in Uganda, for example Okurut et al. (2002), Appleton (1999) are typically concerned with determinants of regional poverty and how poverty has evolved over time. But like other poverty studies so far, it does not examine the distributional impact of trade policies. Apart from DeRosa et al. (2003) that investigates the impact of EAC customs union, empirical work on poverty in Uganda generally fall outside the realm of trade policies.

Uganda is widely known for implementing rigorous economic reforms from the 1980s-1990s, in which trade liberalization was part. Export taxes were removed and import tariffs rates reduced. Control of domestic prices by government ended, and state-controlled enterprises were privatized to reduce government’s involvement in commercial activities. On 30 November 1999, the Treaty Establishing the East African Community (EAC) was signed, bringing the number of regional agreements to which Uganda is a member to two, after COMESA (established in November 1993). Since then, regional integration programmes (EAC, COMESA) continue to drive trade policies in Uganda.

This new policy orientation is evidenced by a marked increase in Uganda’s exports from US$ 196 million in 1991 to US$ 1.34 billion in 2007, while imports rose from US$ 1.73 billion in 2004 to US$ 3.5 billion in 2007. This in turn has generated a new optimism about Uganda’s potential for accelerating economic growth and for reducing poverty. In 1992 (after five years of implementing new trade policies), there was a widespread poverty incidence (of over 50%) all across Uganda. Over 70% of the population in northern Uganda lived below the poverty line (Appleton, 1999). This result was confirmed by the census-based results, which also demonstrated that the central and western region had the lowest levels of poverty (54%) compared with other regions. When other measures of welfare: poverty gap and Gini coefficient are considered, northern Uganda had worsening indices of inequality and poverty gap in the early 1990s.

By 1999/2000, national poverty headcount had declined to 35% from 56% in 1992 (Appleton, 1999; UBOS, 2003a). Over the same period, total trade increased by 95%, from US$ 695.8 million in 1992 to US$ 1.36 billion in 2000. The gains in incomes through increased producer prices of cash crops, particularly coffee in the 1990s, contributed to reducing poverty in 1992 and 2000. Poverty declined throughout western, central and eastern Uganda, where coffee is widely grown. In northern Uganda where agricultural production was interrupted by the effects of war, poverty level remained high (Appleton, 1999; UBOS, 2003a).
However, in 2003, poverty rose to 38% despite the 40.4% increase in total trade between 2000 and 2003. Income inequality (measured by Gini coefficient) also rose from less than 0.39 in 1999/2000 to 0.43 in 2002/03, and continues to widen both in rural and urban areas. Similarly, the depth of poverty (measured by the poverty gap index—the ratio of the average extra consumption required to bring all poor people up to the poverty line) worsened. Poverty gap rose from Ush 711,592 million (€355 million) in 1992 to Ush 581,907 million in 1996 and about Ush 1,200 billion (€571 million: approx. 10% of Uganda’s GDP) in 2002/03.

Recent statistics suggest that since 2003, poverty levels have reduced remarkably, but these official figures were subjected to searching criticism from politicians and academics who argue that it was inconceivable to talk about fall in poverty amongst a population that was surviving on food relief (referring to northern Uganda).1

Against this background, the aim of this paper is to help us understand to what extent Uganda’s trade liberalization in the context of EAC and COMESA trading arrangements (if Uganda were to be a member of COMESA free trade area), and rest of the world (ROW) are likely to impact on the poor. Simply put, what impact is the reduction/removal of tariffs on Uganda’s imports from the EAC likely to exert on the level of poverty in Uganda? Second, what will be the likely impact of removing tariffs on imports from the non-EAC COMESA countries? This second question is important because, at the moment, Uganda is not a member of COMESA free trade area and there have been proposals that Uganda joins the COMESA free trade area. This question facilitates the understanding of what would be the benefits of the actual vis-à-vis contemplated options with regard to Uganda’s membership in COMESA.

This paper adds some new dimension to the understanding of the effects of trade policies on poverty by going beyond the traditional fashion of modelling the relationship between trade and poverty, to actually distinguishing the impact of policies at national, regional and multilateral level, thus presenting policy makers with potentially interesting choices and options to consider.

Objectives of the Study

The major aim of the study was to investigate the impact of trade policies on poverty in Uganda, specifically:

1. The extent to which tariff reductions on imports from the East African Community, COMESA and ROW affect levels of poverty in Uganda;
2. The effects of the reduction in tariffs on prices, production, wages and other key macro variables that affect poverty; and
3. To draw policy implications for regional and multilateral trade in context of poverty reduction in Uganda.

The rest of the paper is organized as follows: in section 2, developments in trade policies in Uganda are presented. Section 3 provides an overview of the CGE micro simulation approach used in trade and poverty analysis, while Section 4 introduces the model, combined with a theoretical framework linking trade and poverty. The empirical results are presented in section 5, while section 6 is the conclusion.
2. Trade policy reform in Uganda

Overview

This section gives a brief account of the trade policy developments in Uganda. It maps out Uganda’s trade relationships in the East African Community (EAC), the Common Market for Eastern and Southern Africa (COMESA), the World Trade Organization (WTO) and with the European Union (EU). It distinguishes between these markets, in which Uganda’s trade faces different conditions, with implications for poverty, and presents policy makers with potentially interesting choices and options to consider.

Unilateral trade reforms

Unilaterally, Uganda has implemented a series of trade reforms in a process that started in the late-1980s as part of structural adjustment programmes (SAPs) with support mainly from the World Bank and the International Monetary Fund. These programmes, anchored in economic liberalization led to: (i) privatization of state-owned enterprises, and encouraging greater participation by the private sector; (ii) removal of domestic price control and subsidies that were used extensively since the 1960s to protect the agricultural sector; (iii) reduction of tariffs on imports (from average of 40% to 30%) and removal of export taxes; and (iv) simplification of customs procedures.

Between the late-1980s to early 1990s, all state-owned agricultural marketing companies, notably the Produce Marketing Board (PMB), Lint Marketing Board (LMB), and Coffee Marketing Board (CMB), which for over 25 years held the monopoly on the purchase and export of agricultural commodities, were disbanded. Encouraged by the rise in farm share of export prices for cash crops in the 1990s, and improved economic performance, Uganda sought to build dynamic export sectors by reforming its overall tax system and exchange regime.2

On border taxes, the myriad tax rates charged on imports were reduced to five bands in 1990/91, and eventually to three standard rates: 0%, 7% and 15% under plant and machinery (capital goods), raw materials and intermediate goods, and finished goods, respectively. Tariff peaks were reduced from over 40% to an average of 10-30% range for most tariff lines as summarized in Table 1 for the year 2004 and 2005.

The mark-up applied on the value of imports – for sale tax valuation – was reduced and eventually eliminated. The temporary export stabilization tax on coffee exports was also removed. Incentives were targeted at export-oriented sectors to encourage diversification into traditional and non-traditional exports.

Note: the 2004 tariffs include excise taxes and import commissions. The data in Table 1 gives the impression that Uganda tariffs went up, on average after 2004, which is not the case. This is influenced by high tariffs of a few sensitive tariff lines (sensitive products). Readers can have a better picture by looking at ‘all categories’.

Export/import-licensing requirements were replaced (in September 1990) with export/import certification system and import controls, with tariff-based protection. Customs formalities have been reduced to, essentially, commercial invoice. It is only in exceptional cases that health and phytosanitary certificates are required. Pre-shipment inspection was largely abolished.

A market-based inter-bank foreign exchange market (IFEM) system replaced the state-controlled “window” and auction system of the 1980s, reducing volatility in exchange rates and bias towards traditional export sectors. Traditional export sectors (coffee, cotton, tea and tobacco) were allocated foreign exchange through window one, the priority window. “Window two”, which majority of traders used, had its exchange rate set through weekly auction by Bank of Uganda. Moreover, exports retention scheme operated under very stringent conditions, making it difficult for exporters to retain foreign currency to pay for imports.

By 2004, Uganda was still levying 2% import commission on all imports, on top of the 10% excise duty (applied on an ad valorem basis across about 400 tariff lines). In addition, 17% value-added tax (VAT) was charged on a range of imports. Further to these, most of the statutory instruments had the flexibility to allow raw materials for specific industries to be imported at preferential rates, for example by remitting the customs duty payable from 15% to 7%. The sugar industry benefits simultaneously from high duties on sugar imports, and preferential access to imported sugar as a raw material for other production (beer and soft drinks). These preferences were withdrawn prior to the EAC customs union. The cost of inland freight also ceased to be part of the base for valuation of imports.

Trade policies in the context of EAC integration

In January 2011, the implementation of the EAC customs union entered its seventh year, having come into force on 1st January 2005. Since then, EAC partners have
adopted a common external tariff (CET) to 5,429 tariff lines (at the HS 8-digit level), of which 99.8% carry ad valorem duties. The CET comprises three bands: 25% for finished goods, 10% for semi-processed or intermediate goods, and zero-rate for raw materials and capital goods, except for sensitive products. These three rates apply to about 99% of overall tariff lines, with the top rate accounting for about 40% of existing tariff lines as illustrated in Figure 1.

**Figure 1: EAC common external tariff**

![Figure 1: EAC common external tariff](image)

Source: WTO Secretariat calculations based on data provided by the EAC country authorities
Note: The EAC members were expected to review the maximum rate of the CET after 1 January 2010.

The remaining 1% of the overall tariff lines (i.e., 58 tariff lines)—excluded from the CET—is for “sensitive products”. They attract “special tariffs”. About one-fifth of these tariffs are combined duties. *Ad valorem* rates vary from 35% duty on matches and battery cells to 100% duty on sugar imports. Other products on the sensitive list include dairy products; wheat; maize; cigarettes; cement; *kangu*, *kikoi*, and *kitenge* fabrics; crown cock; sack and jute bags.

Sensitive products constitute important features of the EAC tariff structure. In the model, tariffs on EAC imports, including sensitive products, are set to zero (section 5.1). The data on Table 2 suggests that the five major sensitive products account for at least 5% of Uganda’s imports, annually.

Another important feature of the EAC tariff structure is the exception for the lesser developed members of the EAC, including Uganda, who were not expected (at least up to 2010) to fully liberalize. This exception applies to category “B” goods exports from Kenya to Uganda and Tanzania for 443 and 880 tariff lines, respectively. These goods attracted 10% import duty on entry into Uganda and Tanzania in 2005. Beginning 2006, the duty was to be phased out progressively, down to zero in 2010. The same applies to the new EAC partners (Burundi and Rwanda) whose schedule of accession allows them until 2010 to bring their tariff regimes in conformity with the customs union protocol.

EAC remains an important market for Uganda (Table 3), accounting for a significant share of over 21% of total exports in 2010. Considering that more than half of these exports comprise agricultural products – mainly maize, fish, tea, and vegetables – that employ over 40% of the poor, removing intra-EAC tariffs has the potential to reduce poverty if it results in growth of such sectors. Clearly, potential for expanding Uganda’s exports in the EAC market exists, as the trends in Table 3 suggest. The structure of imports is also expected to have a positive impact on poverty because it covers mainly manufactured goods other than agriculture, where majority poor are employed.

The downside of EAC tariffs removal is the huge loss in government revenue. Most of these losses are expected to come from manufactured imports, textiles, sugar, cooking oil, oil seeds, dairy products, crude materials and chemical imports (Table A3). For example, tariff revenue from manufactured products alone fell by 71% between 2005
and 2007 (i.e., from Ush 308.594 billion to Ush 90.145 billion). As we notice in Table 4, duty revenue on imports from EAC declined from Ush 338.5 billion in 2005 to 142.8 billion in 2007. Without temporary tariffs, Uganda will, in aggregate, lose about 35% of total duty revenue.

Trade policies in the context of COMESA regional arrangement

Unlike in the EAC market, Uganda’s exports face tariffs of 4-6% in COMESA market (outside EAC) for most goods. Similar goods from COMESA face the same tariffs in Uganda (Uganda’s tariff preferences with COMESA countries originally extended to over 700 goods). In the model, these tariffs are set to zero and the simulated effects demonstrate the likely impact Uganda’s membership to COMESA free trade area would have on the poor in Uganda.

Uganda is a founding member of the Common Market for Eastern and Southern Africa (COMESA), established in November 1993 as a successor to the preferential trade area (PTA) for Eastern and Southern Africa. Of the current membership of 19 countries,8 13 are a free trade area (FTA),9 while six members, including Uganda, are not in the FTA. As a founding member, however, Uganda can export to COMESA at tariff rates 60-90% below the COMESA CET, on a reciprocal basis. In the model, the tariffs on COMESA imports are set to zero to explore the alternative option of joining the COMESA FTA.

Uganda’s major exports to COMESA include manufactured products, coffee, sugar, fish, and cereals. Increase in export of these goods is expected to have a positive impact on poverty because the exported products support rural income. Imports from COMESA, outside of EAC, account for less than 2% of Uganda’s total imports, and are mainly manufactured products. These rates (share of exports and imports) are expected to rise with complete phase-out of intra-COMESA tariffs, and the effects on the poor will depend on whether the cost of the consumption bundle falls more or less than their wages/income.
Trade policies under the EAC-EPA arrangement

The European Union is the single largest market for Uganda’s goods, accounting for about 30% of Uganda’s total merchandise exports in 2010 against 21% of total imports in 2010. Uganda’s major exports to the EU include fish (fish products), coffee, tobacco (tobacco products) and cotton, and imports from the EU manufactured goods, textiles, wheat, and other cereals (Table A2). Being a Least Developed Country (LDC), Uganda is allowed (under the EU’s Everything But Arms Initiative), duty-free, quota-free access to the EU market, while EU’s exports to Uganda are subject to the EAC common external tariffs (CET). The European Commission and the EAC partners have sought to establish a free trade area between them. Upon entering an interim economic partnership agreement on 27 November 2007, 31 December 2007 was set for a full agreement, as WTO waiver on the non-compatibility of the EU preferential trade relations with ACP countries would expire by then. By March 2011, the possibility of signing a full agreement seemed far from sight as the parties failed to agree on issues of development concerns to EAC and on the Most Favoured Nation (MFN) clause, among other issues.

The EAC-EU interim partnership agreement requires the EAC partners, including Uganda, to gradually liberalize 80% of their trade for imports from the EU. The liberalization, covering mainly capital goods, raw material and intermediate/industrial goods is to progress over a period of 15 years (attaining full liberalization over a period of 25 years). Although agricultural products, wines and spirits, chemicals, plastics, wood based paper, textiles and clothing, footwear, and glassware are excluded from liberalization, eliminating tariffs on EU manufactured imports alone will considerably lower tariff revenues. For example, in 2007, manufactured imports from the EU generated Ush 106.361 billion in tariff revenue (Table A3).

Trade policies under the GATT/WTO context

Liberalizing Uganda’s trade in the context of GATT/WTO trading arrangement (as considered in the model) extends tariffs reduction beyond imports from regional trading partners to include imports from rest of the world (ROW). Uganda has been a GATT contracting party since independence (October 1962), after acquiring the GATT rights and obligations previously accruing to the United Kingdom with respect to its territory under the trade "succession" procedures. On 29th September 1994, Uganda ratified the Marrakech Agreement to become a founding member of the World Trade Organization (WTO). As a least developed country, Uganda is not expected to take on WTO liberalization commitments of cutting down its tariffs, and the purpose of reducing tariffs on ROW imports in the model is to demonstrate the potential impact of liberalizing Uganda’s trade for imports from WTO members.

In the model, the rest of the world (ROW) includes the EU and non-members of the EAC and COMESA. Between 2005 and 2007, Uganda’s total merchandise trade with ROW accounted for a share of 75% of its overall trade annually, comprising exports (18%) and imports (57%). Imports have tended to increase faster than exports, and this will deepen the balance of trade problem in case of reduction on ROW tariffs, with significant implications for poverty in Uganda. Uganda’s major exports to ROW include
coffee, fish/fish products, cooking oil (fat), oil seeds, tobacco and tobacco products, manufactured products, cotton and vegetables. Its major imports from ROW include capital goods (manufactured products), wheat, textiles and clothing, cooking oil (fat), oil seeds, sugar, and food items. In value terms, imports from ROW are 5 times Uganda’s exports to ROW.

Table 4 shows that about 70% of total tariffs revenue in 2007 was collected on imports from ROW. Most of the revenue losses are expected to be from manufactured imports, which generated Ush 532.606 billion in tariff revenue in 2007, textile imports (Ush 47.212 billion), sugar (Ush 37.583 billion), and beverages 5.1 billion in 2007.

The data in Appendix (Table A1–A3) provide some numerical insights, which are useful for understanding the results in section 5. In the next section, we turn briefly to the CGE micro simulation approaches commonly used in analysis of the impact of trade reforms on poverty.
3. An overview of micro simulation approach

Computable General Equilibrium (CGE) model has been used in poverty analysis for a long time, for example by Adelman and Robinson (1978) for South Korea. The second impetus to this literature can be identified with the OECD sponsored projects on the impact of structural adjustment programmes on income distribution in Indonesia (Thorbecke, 1991), Ecuador (de Janvry et al., 1991), and Morocco (Morrison, 1991). Since then, there has been a steady growth in literature on the link between trade policies and poverty, based on CGE models.

These CGE models have taken either the representative household approach (the most widely used approach), pioneered by Adelman and Robinson (1978), the integrated multi-household approach (IMH) applied by Decaluwé et al. (1999), or top-down/micro-simulation sequential approach (MSS).

In the representative household approach, only representative household sub-groups are included in the CGE model. Changes in the income of all households within each group are then inferred based on the changes of income of the representative households in the model. This approach is a bit simple because it does not require any modelling effort outside what is done in standard CGE modelling exercise (Savard, 2005). Its downside is that it fails to take into account the within-group redistribution of income, and can easily lead to misleading conclusions (Savard, 2005; Boccanfuso and Savard, 2005).

The integrated multi-household (IMH) approach includes all households, or a large number of households, from household survey in the CGE model. It accommodates intra-group changes and does not require household grouping or aggregation. This way, the controversy associated with household aggregation is avoided.10 However, with such a large size of model (incorporating all households), numerical resolution as well as data reconciliation can be challenging (Boccanfuso and Savard, 2005; Chen and Ravallion, 2004).

With the top-down or micro-simulation sequential (MSS) approach, a CGE model is used to generate price changes that are fed into a micro-simulation household model. The first step is to introduce shock to get commodity and factor price changes. The new prices are then fed into a post-simulation framework that calculates the effects on actual or highly disaggregated representative households. Various poverty measures can then be applied to assess the distributional effects of the shocks (Reimer, 2002). An example (of the top-down method) is the macro-accounting method proposed by Chen and Ravallion (2004), and used extensively in recent years.

The top-down approach fully accounts for household behaviours and remains extremely flexible in terms of behaviours that can be modelled. Its limitation is that it
does not (fully) take into account the micro-feedback effects; that is, the reactions of households to changes in commodity and factor prices are not transmitted back to micro-simulation model. Only a fraction of the intra-group inequality is captured (Hertel and Reimer, 2004; Bourguignon and Spadaro, 2005).

The approach relevant for this study is one that incorporates household data in the CGE model and simulates the model with all the individual households (Cogneau and Robilliard, 2000). The same approach was used by Cockburn (2001) to analyze the impact of trade liberalization on poverty in Nepal. He endogenises intra-group variations by incorporating all the households from a nationally representative survey. Cockburn’s findings, as seen by many analysts –e.g. Chitiga et al. (2005) – lend support to the view that micro simulations are very important for poverty analysis. After him, Cororaton (2003) used the same approach for the Philippines with 24,797 households, and Chitiga et al. (2005) for Zimbabwe with 14,006 households. They were able to carry out comprehensive poverty and income distribution analysis.

Decaluwé et al. (1999) compare results of poverty and income distribution using the three different CGE approaches reviewed above. The results suggest that the integrated multi-household approach (use of household data into the CGE model itself) is superior to all others in terms of comprehensive analysis of poverty. The results are also confirmed by Savard (2005). Thus, it is a worthwhile exercise for poverty analysis.
4. Model development

Theoretical linkages

Trade theory suggests several channels through which tariff changes affect the poor. Important ones are: effect on relative prices of traded goods on employment and wages (income), structure of consumption, and on government revenues.

We expect price effects to dominate trade policy shock and to be driving poverty in Uganda. The population that will either slide into poverty or be lifted out of poverty as a result of a policy shock are assumed to be those whose incomes are close to a monetary poverty line. We define this poverty line as the cost of a basket (of quantities) of different commodities indexed as $b = (b_1, b_2, ..., b_n)$ reflecting basic needs consistent with Ravallion’s (1994) approach to estimating absolute poverty – the “cost-of-basic needs” method.

This basic needs basket “$b$” applies to all households and remains invariant from one policy simulation to another. Prices of the commodities in the basket are represented by $p = (p_1, p_2, ..., p_n)$. The population below the poverty line remains at base level before a policy shock. However, if composite commodity prices ($p_i$) rise following an external shock, the cost of the basic needs basket, hence the poverty line PL, will increase and the population below the poverty line will rise ceteris paribus.

We consider Uganda to be a small country, which does not exert an influence on the world price of exports ($P_{Xw}$) and on that of imports ($P_{Mw}$). We represent prices of imports (including tariffs, ) in domestic currency by:

$$PM_i = (1 + t_{Mi}) . ER . P_{Mw_i}$$

and quantities of imports by:

$$M_i = \gamma_i \frac{p_i}{P_{M_i}} \delta_i X_i$$

where ER is exchange rate; $M_i$: quantities of imports; $p_i$: prices of composite commodities; $\gamma_i$: CES distribution parameter of Armington function; and $\delta_i$: elasticities
of substitution of Armington function. The domestically produced commodities delivered to home market and imports combine to form composite commodities $X_i$ by means of CES function.

Following a tariff cut (holding nominal exchange rate fixed), domestic price of imports ($P_M$) will fall. Prices of domestically produced commodities delivered to home market (and prices of composite commodities) are expected to fall due to rise in demand for imports, which suppresses demand for domestically produced (import-substitute) goods,

$$XD = \gamma_i \left( \frac{p_i}{PD_i} \delta_i X_i \right) + X_i$$

where XD is domestic demand for domestic output, and $PD_i$: prices of domestic output delivered to home market. Prices may fall for some of the commodities in the basic needs basket, and rise for others depending on whether they are import-substitute goods, among other factors.

If price of exports ($PX_w$) remains unchanged, labour and capital in the import-substitute sector may be hurt in the short run. If the imports concerned are inputs to other goods rather than for sale to consumers, domestic production of goods using the inputs may increase. This causes changes in relative factor demands, depending upon the relative factor intensities used in different sectors.

Based on Heckscher-Ohlin theorem, we would expect that Uganda, as an economy relatively endowed with unskilled labour, would have its abundant unskilled labour aided by trade liberalization. The incomes of the poorest groups in Uganda (quintiles 1 and 2) are mainly composed of unskilled labour payments (Table A4). Table A5 reports the share of the primary factors of production in value-added for each productive sector in Uganda. Apart from the manufacturing and services sectors, most sectors including agriculture, are intensive in unskilled labour. This suggests that a shock that affects labour allocation in agricultural sectors is likely to affect rural incomes, especially among the unskilled wage earners.

If the changes in tariffs on consumption goods cause the relative price of unskilled labour intensive goods to increase, we would expect, as the Stolper-Samuelson theorem predicts, an increase in the wages of unskilled workers (hence reducing poverty if it is large enough to move some households above the monetary poverty line).

**Features of the model**

A Computable General Equilibrium (CGE) model is calibrated to a 2002 social accounting matrix (SAM) for Uganda (Alarcon et al., 2006). In its original form, the SAM consisted of 74 production branches/commodity sectors and activities, 32 household groups, and 18 factors of production and one foreign market (ROW). To keep the model tractable, we modified the SAM to 36 production branches/commodity sectors and activities, 18 household groups, and 18 factors of production and one foreign market (ROW).

The 9,711 households from the 2002/03 national household survey were incorporated into the SAM by entering data related to the final consumption of individual households (in terms of commodities), income by economic activity, etc, from the survey, into the SAM (and balancing sum of consumption, income, etc over all households with the row/column totals for households in the SAM). For example, in the account “households”, we entered, row-wise, the resources that are at the disposal of each household viz. its revenues from capital and labour, and the transfers from the government (pension benefits), corporations (pension and social security paid by firms), and transfers from other households. Column-wise, we entered expenditures of each household. In the block (Commodities, Household) we entered the expenditures on the consumption of commodities at market prices. In the block (Taxes on income, Household) we entered the taxes on income paid by individual households. Finally, in the block (Savings, Household) we entered household’s savings.

Government expenditures in the model are funded from tariff revenues and revenues from indirect taxes (modelled as a value-added tax, ‘VAT’ and income tax, ‘Ytax’). Tariffs and taxes on commodities, labour, capital, household income, and corporate income are given as fixed ad valorem rates. Tax revenues and income transfers received by government from ROW, including international aid, are used to meet government demand for commodities, to pay wages and capital, and to deliver public goods, including transfers (pension) and subsidies to households and other institutions. The government’s budget balance (public savings) is endogenously determined. With expectation that tariff revenues will decline ceteris paribus, the model allows increase in VAT and Ytax to ensure revenue neutrality.

Each of the 36 production sectors of the domestic economy utilises a nested production technology. Commodities are produced using skilled and unskilled labour, intermediate inputs, capital and land. In the SAM account for “sectors”, we entered, row-wise, the sales of the domestically produced commodity to the domestic market and to the foreign markets (EAC, COMESA and ROW). Column-wise, we included the inputs required for domestic production of the domestically produced commodity. The value added is equal to the remunerations of the factors of production: capital, labour and land.

Labour is assumed to be mobile across sectors. However, unskilled agricultural workers can be employed only in agriculture, while skilled workers are mobile between agriculture and non-agricultural sectors. The combination of labour in production is modelled according to constant elasticity of substitution (CES) function. In equilibrium, wages serve to equate demand and supply of labour. Capital is considered to be sector-specific, and primary factor supplies are exogenous to the model. The demand for intermediate inputs and value added are modelled as fixed proportions of total output. The components of value added are aggregated using a CES function. The transformation of domestic production into exports is modelled according to the CET function.

Exports are shared between the EAC, COMESA, and the rest of the world (ROW) markets. This relationship is characterised by three different CES function:
Export supply, \( Q_E^c = Q_D^c \left[ \frac{P_E^c}{P_D^c} \cdot \frac{1 - \delta^q_c}{\delta^q_c} \right]^{\frac{1}{\rho^q_c - 1}} \) \( (4.1) \)

where \( Q_D^c \) is quantity sold domestically of domestic output \( c \); \( P_E^c \) is export price for commodity \( c \) (in domestic currency); \( P_D^c \) is domestic price of domestic commodity \( c \); \( \delta^q_c \) is Armington function share parameter; and \( \rho^q_c \) is Armington function exponent. Export supply in each of the three foreign markets is determined by demand, and the price received by producers is given in domestic currency.

Similarly, importers have the option to import commodities either from the EAC, COMESA, or ROW according to Armington substitution elasticity (CES) function. Imported and domestic goods are assumed to be imperfect substitutes (Armington, 1969). Domestically produced and imported goods combine to form a CES aggregate:

\( QQ^c = a^q_c \left( \delta^q_c \cdot QM^c \rho^q_c \right) + \left[ 1 - \delta^q_c \right] QD^c \rho^q_c \left( \frac{1}{\rho^q_c - 1} \right) \) \( (4.2) \)

where, \( QQ^c \) is quantity of goods in domestic market; \( a^q_c \) is Armington function shift parameter for commodity \( c \); and \( QM^c \) is quantity of import:

\( QM^c = QD^c \left[ \frac{P_D^c}{P_E^c} \cdot \frac{1}{\left( \frac{1 - \delta^q_c}{\delta^q_c} \right)} \right]^{\frac{1}{1+\rho^q_c}} \) \( (4.3) \)

The domestic import price is the world price adjusted by the exchange rate and import taxes. Therefore, changes in tariffs cause changes in the composite prices of the traded goods. The model allows tariff rates to differ depending on whether the imports are from the EAC, COMESA or ROW. Importers/consumers are expected to allocate their expenditure on EAC, COMESA and ROW imports, and each allocation decision is modelled as a CES function.

Output \( QX^c \) is distributed between domestic market and export markets (EAC, COMESA and ROW). In the domestic market, the good is sold to households, government, or used as intermediate inputs or investment goods. Indirect taxes are added to the local (producer) price to form domestic prices which, together with the import price form the composite price of domestically consumed goods via a CES function (equation 4.4).

\( QX^c = \beta^t_c \left( \delta^t_c \cdot QE^c \rho^t_c + \left[ 1 - \delta^t_c \right] QD^c \rho^t_c \right) \left( \frac{1}{\rho^t_c} \right) \) \( (4.4) \)
where $Q_X^c$ is aggregate domestic output of commodity $c$; $\beta_c$ is CET scale parameter; $\delta_c^t$ is CET elasticity of transformation; $QE^c$ is quantity of exports, and $\rho_c^t$ is constant elasticity of transformation (CET) parameter. Export price is affected by output price, which in turn is affected by input prices. Export prices may vary across the three markets: EAC, COMESA and ROW.

As referred to already earlier, household income comprises wages, profits from rent of capital, and transfers from government, firms, other households and rest of the world (remittances). Besides savings, households use part of their income to pay taxes, pay other households or institutions (transfers), and to pay for goods and services.

Final demand by each household arises from nested constant elasticity of substitution (CES) utility function subjected to the budget constraint, determined via a linear expenditure system (LES), which allows different marginal budget shares for different households to be included.11

That is,

$$C_{ch} = \frac{p_c b_c + \beta_{ch} (Ch \cdot \sum_{j=1}^{J} p_j b_j)}{p_j}$$

(4.5)

where $C_{ch}$ is demand for commodity $c$ by household $h$; $p_c$ : price of commodity $c$; $b_c$ : quantity of commodity $c$ in household basic needs basket; $\beta_{ch}$ is share of commodity $c$ in the consumption of household $h$; $Ch$ is total household consumption; $p_j$ are unit prices of different commodities in the household basic needs basket; $b_j$ : quantities of commodities in basic needs basket (these quantities are fixed, apply to all household groups and remain invariant from one simulation to another); and $p_j$ : prices of composite commodities.

$\sum_{j=1}^{J} p_j b_j$ = the monetary value of the minimum consumption (monetary poverty line), determined endogenously within the CGE model. Each household is assumed to behave in such a way that it first satisfies its minimum consumption of the respective commodities. Changes in the composite prices induced by changes in tariff rates will affect cost of basic needs basket, and therefore rate of poverty. A number of general equilibrium responses triggered by these price changes (e.g. changes in wages, composition of output, exports and imports; and pattern of employment) are captured in the model. These endogenous variables ultimately impact on poverty. A Foster-Greer-Thorbecke (F-G-T) poverty measure due to Foster et al. (1984) $P_\alpha$ is used to compare poverty (pre- and post-simulation experiment).12

Finally, demand for each composite good is assumed to equals supply of such good. Demand for exports equals supply of exports; and total investment equals savings. The world prices of imports and exports, the current account balance, and nominal exchange rate are exogenous to the model. Flexible prices serve to clear the markets for all commodities and factors. The macro closures apply to the government, the savings-investment balance, and external markets (EAC, COMESA, and ROW).
Model closure

Nominal government expenditure is equal to fixed quantities of consumption goods multiplied by their endogenous prices. Fixing real government expenditure insulates the poverty-related variable from the influence of government spending. Government income is held at base level, so that any reduction in government income from tariff cuts is compensated endogenously by additional revenue from value-added tax (VAT) and income tax (Ytax).

The basic needs basket of commodities for the poor in Uganda consists mainly of unprocessed foodstuffs. Introducing replacement taxes may not increase the cost of the unprocessed food component of the basic needs basket, as this component does not attract taxes. That is, supply of basic foods such as unprocessed foodstuffs, unprocessed agricultural products and livestock, and cereals (grown, milled or produced in Uganda) are exempted from value-added tax.

Total nominal investment is equal to fixed quantities of investment goods multiplied by their endogenous prices. The propensities to save of individual households adjust proportionately to accommodate the fixed total real investment formulation. This is achieved through a factor in the household saving function, which adjusts endogenously.

The current account balance is exogenous (foreign savings is equal to foreign account deficit) and the nominal exchange rate is the model’s numéraire. Flexible foreign savings serve to clear the current account balance. As long as the nominal foreign exchange rate is fixed, the presence of foreign savings/exchange rate does not influence the savings-investment closure of the model, according to which the savings value determines the investment value. Real exchange rate is equal to nominal exchange rate multiplied by the world export prices, divided by the domestic price index. Changes in real exchange rate (due to variations in export prices) effectively clear the foreign trade sector.

In the factor markets, wages clear the labour market, and a fixed capital use for each activity is assumed. We assume some unemployment with fixed, activity-specific real wages for labour. Besides capital, land is fixed in the short run, and technical change and other shift variables are assumed to remain constant. Walras law is satisfied since private consumption equals the income from primary factors plus net transfers to households (consumers) by government from domestic and international trade taxes.

Data limitations

The household survey exhibited some gaps in data on wage rates and income by economic activity, net savings of the households, and inter-household transfers within the domestic household sector. These were estimated based on other related survey information. Some of the commodities in SAM (e.g. trade services, railway transport, goods road transport and other transport services) and factor income transfers from ROW to the domestic household sector were not accounted for in the household survey. Expenditures on these commodities have been allocated to each household according
to some expenditure share criteria. Second, reconciling data was very challenging as a result of incorporating a large number of households into the SAM. This led to adjusting some figures (especially inter-household transfers, consumption expenditures, income, etc) in view of considerations to balance the SAM. However, the order of magnitude of missing/unreliable data and related adjustments made are within reasonable limits and, as such, we do not expect it to affect the model/results significantly.
5. Empirical results and discussions

Policy simulations

Three types of policy simulations are performed, in line with the model closure described above. First, the weighted average of EAC tariffs is set to zero, i.e. imports from EAC enter Uganda free of duty, including category B goods exports from Kenya. The reason for including category B goods is to avoid the modelling difficulties associated with isolating these goods in the model. Considering that the 10% tariff on category B goods was a temporary measure to be phased out in 2010, applying uniform condition to EAC imports is appropriate. In the second simulation, the average weight of non-EAC COMESA tariffs is set to zero (i.e., imports from COMESA countries enter Uganda free of tariffs). The purpose of the second simulation is to demonstrate the likely impact that Uganda’s membership to COMESA free trade area would have on the poor in Uganda. In the third simulation, tariffs are set to zero across the board (i.e., EAC, COMESA and ROW imports), including sensitive products (compared with a scenario in which all tariffs, but sensitive products are set to zero). Although this simulation is not identical to what happens in the real world, the purpose is to demonstrate the potential effect of complete tariff reduction.

In what follows, we first present the sectoral and macro results arising from these simulations, such as the reaction of imports, domestic prices, output and wages in the economy as they are key variables that affect poverty, and then results related to poverty.

Simulation 1: Reduction in EAC tariffs by 100%

Simulating 100% tariff reductions on EAC imports is associated with a rise in EAC imports across all sectors as reported in Table 5 (see Table A6 for full sector coverage). The highest increase in imports occurs in the dairy, beverages and textile sectors, which also happen to be highly protected sectors. Sources such as the Uganda Revenue Authority have also indicated that Uganda’s imports from the EAC, particularly of dairy products, beverages and textiles have been growing steadily in recent years. This implies that, with complete phase out of intra-EAC tariffs, protected sectors are likely to contract due to rise of imports, and non-protected sectors to expand. We are likely to see decline in food imports from COMESA, but imports of beverages, sugar and manufactured products from COMESA and ROW are likely to rise, at least in the
short run, independent of existing tariffs. Rise in cereals imports from EAC (estimated at 1.1%) and imports of other food commodities (vegetables, legumes, sesame, etc) estimated at 2.6% suggests that removal of intra-EAC tariffs is likely to impact these sectors less than most sectors.

Note: 1/ sesame, vegetables, fruits, spices, groundnut, and other foodstuff; 2/ coffee, tea, tobacco, cotton/textile

The modest rise in cereal imports of 1% (from EAC) has been more than compensated by a 3% fall in cereals imports from COMESA. Cereal imports from rest of the world went up by 1.8%. The fall in COMESA imports suggests that the complete phase-out of intra-EAC tariffs is likely to suppress imports of cereals and agricultural food from non-EAC COMESA countries. Imports from COMESA and ROW are predicted to fall in a number of sectors as a result of reducing EAC tariffs to zero. This is expected because COMESA and ROW imports will be competing with imports from EAC region that do not face the same tariffs in Uganda.

We expected the manufacturing imports (from the EAC) to grow by over 4.3% (Table 5) after the simulation, as manufacturing sector is relatively protected. This result suggests that although imports will rise after removing intra-EAC tariffs, the rise is likely to be rather modest in scope, in the short run. As such, the manufacturing sector in Uganda may not necessarily suffer adverse effects due to this reform.

In Table 6, we see that the effect of complete phase-out of intra-EAC tariffs remains positive for domestic production and domestic prices in most sectors. Overall, two sectors face fall in production: beverages (-17.1%) and fish sectors (-2.4%). Prices remain nearly unchanged for dairy, but fall for beverages and traditional cash crops: coffee, tea, tobacco and cotton. Rising levels of imports exert pressure on domestic prices of beverages, causing them to fall. Fall in prices in turn led to fall in domestic production (Table 6). This should come as no surprise, for the beverages sector happens to be among those sectors that were highly protected and relatively subsidized (e.g. imported sugar used in production of soft drinks at 7% duty instead of 17%).

On the dairy sector, available evidence indicates that the quantities of dairy imports as share of composite supply in the domestic market or of domestic production are quite
low. As a result, domestic production and prices (in the dairy sector) are not affected (Table 6).

Note: 1/ and /2 as in Table 5

The domestic prices and production of cereals are hardly affected after this simulation because of the small increase in cereal/food imports and due to the fact that such imports contribute very small shares (less than 3%) of total supply of composite commodities in the domestic market. The neutrality (or near neutrality) of Uganda’s food sector to EAC tariff reforms is helped by the fact that Uganda is a major food producer/net food exporter in the EAC.

The rise in domestic prices of fish is attributed to a fall in fish production. The fall in fish production could have been triggered by changes in relative prices, but not necessarily the rise in fish imports (7.6%), which we saw in Table 5.

The domestic price of sugar went up despite the rise in domestic production and imports. This is due to increase in export demand (Table A7 reports a 45.2% rise in sugar exports to the EAC market). Real exchange rate depreciates, leading to increase in exports. Prices of cereals and other food commodities have equally gone up after simulation. Available sources show that Uganda’s food exports to the EAC region have increased dramatically in recent years.

Following a complete phase out of the EAC tariffs, demand for unskilled labour increases in all sectors, except in fish and beverages sectors. Where the relative price of unskilled labour intensive goods have increased (as the Stolper-Samuelson theorem suggests), we expect the wages of unskilled workers to go up. For fish and beverages sectors, demand for unskilled labour falls by 2.5% and 2.1%, respectively. Demand for skilled labour also drops in primary sectors (livestock, cereals, and other food production sectors) that are intensive in unskilled labour. This situation also shows a drop in unskilled sector wage in the livestock, traditional agricultural cash-crops sector, and beverages sector as demand for unskilled labour increases marginally or drops in some cases.

Increase in sector wages for unskilled workers (highest, as compared to other sector) reported in the food crops sector (cereals, sesame, vegetables, fruits, spices, groundnut, soy bean, etc) is due to increase in relative price of these commodities, which are intensive.
in unskilled labour. The highest cut in sector wages (5% skilled wages and 9% unskilled) is seen in the beverages sector. This policy situation has relatively marginal effect on skilled sector wage, which remained within an average range of -2.4 to 5 percentage change (except for beverages). Although wages for skilled sector workers appear to be more stable than unskilled sector wages, unskilled labour is likely to gain from wage increases (as tariffs on EAC imports go down) than skilled labour.

Note: 1/ and 2/ as in Table 5

Removing tariffs on EAC imports enhances exports. Exports to EAC markets increase in 27 out of the 36 sectors reported in Table A6. The top five export growth sectors include sugar (with 45% rise in exports), wheat (39%), cooking oil/oil seed (38.5%), manufactures (38%), and rice (35.4%). Uganda’s exports growth in the COMESA market as predicted by the model is led by sugar. In the ROW market, coffee, at 38.7% export growth ranks first among Uganda’s fast growing export sectors followed by tobacco (30.5%), and cooking oil (21.9%).

The general rise in level of production across sectors, which we noticed earlier, is in a way export-driven. The opportunities created in the export markets outweigh the negative effect arising from increased imports, as more goods than before can be exported. This situation is likely to spur domestic production in the medium term to long term, and unskilled workers especially in rural areas will gain, as we saw before, from a rise in their wages.

There is therefore a basis, from the evidence so far, for arguing that a complete phase-out of intra-EAC tariffs have little effect on sectors where most poor in Uganda derive their livelihoods, and therefore unlikely to increase poverty. Instead, it seems to offer new avenues for poverty reduction through its potential to stimulate exports, increase unskilled sector wages, and lower prices of other importable goods consumed by the poor.

With regard to government revenues and poverty, these are discussed in the end in sections 5.5 and 5.6. As discussed before, the model ensures revenue neutrality by allowing increases in VAT and income tax to compensate for any potential shortfall in revenue. However, to gauge the effect of tariff reduction on revenue, we relaxed the neutrality assumption, including changing some closure rules and re-run the simulation. We noted an overall loss in government revenue by a ratio of 13.2%. Finally, removing
tariffs on EAC imports (see section 5.6) is generally pro-poor since it lowers the cost of the basic needs basket for the poor, thus monetary poverty line by 2.76%.

**Simulation 2: Reduction in COMESA tariffs by 100%**

In this second scenario, we simulated a 100% reduction in COMESA tariffs. The results in Table 8 (and Table A6) show that Uganda’s imports from COMESA increase after the simulation, but the increases are modest in scope for a number of sectors. Imports of tobacco (from COMESA) grew by 19.8% after the shock, manufactures by 16.5%, sugar 15.9%, poultry and poultry products 15.3%, and bottled water 13%.

Note: 1/ sesame, vegetables, fruits, spices, groundnut, and other foodstuff; 2/ coffee, tea, tobacco, cotton/textile

One would argue that imports (from COMESA) are growing from small bases and, therefore, any small change tends to be magnified. The 5.3% and 9.0% decline in cereals and vegetables imports from COMESA (Table A6) are due to protected sectors (sensitive products) and exchange rate depreciation. Cereals and vegetables are very important in basic needs basket of the poor in Uganda. Table A6 tends to suggest that, while reducing tariffs on COMESA imports will invite more imports from the COMESA region, these imports are likely to be concentrated in few sectors, especially outside the sensitive tariff lines.

The effect on domestic prices of removing COMESA tariffs is negligible (Table 8). This seems to suggest that the rise in imports from COMESA due to tariff changes do not impact the level of domestic supply significantly enough to exert pressure on domestic prices. It follows, therefore, that the gains that the poor might derive from this policy in terms of reduced prices is relatively small, compared with that we saw in the case involving removal of intra-EAC tariffs. The gain to the economy comes from the rise in exports (Table A7) of rice (35%), cooking oil (40%), sugar (46%) and wheat (39%). The poor employed in this sector will experience a rise in their incomes – to the COMESA markets.
Simulation 3: Reduction across the board of import tariffs by 100%

Two simulations are performed as follows: (i) tariffs are set to zero on all imports from EAC, COMESA and ROW, including sensitive products; (ii) tariffs are set to zero on all imports, except sensitive products. As we mentioned in the previous section, Uganda, being an LDC, is not expected to take on WTO liberalization commitments of cutting down its tariffs. The purpose of these simulations is to demonstrate the potential impact of fully liberalizing Uganda’s imports.

Imports increase for most sectors after setting overall tariffs to zero (Table 9). Rest of the world imports grew faster than EAC or COMESA imports. For example, sugar imports from ROW rose by 26.5% after simulation, compared with 5.9% and 18.4% rise in sugar imports from EAC and COMESA, respectively. Another important observation (from the results in Table 9) is that higher increases in imports are associated with sectors that were highly protected (or sensitive products), for example sugar, rice, wheat, textile, and manufactures.

However, when original tariffs on sensitive products were maintained in the model, the increase in imports, especially of sensitive products, were about 50% lower than the rates achieved by setting the tariffs (on all products including sensitive products) to zero. For example, 19% increase in sugar imports was achieved with zero tariffs on sugar imports, compared with 9.2% increase in sugar imports by maintaining the original 100% duty on sugar imports (Table 9). However, textiles are more resilient to tariffs than any other sensitive products. Textiles imports are estimated to increase by 35.1%, with zero tariffs on textile imports and by 32.4% with 35% (average) duty on textiles.

The fall in domestic prices observed in Table 9, particularly for manufactured products, textile, and beverages arise from increased imports. Increase in imports push the prices of domestically produced import-competitive products down. Compared with the EAC tariff reform discussed in section 5.2, the sector price effects associated with current scenario (involving 100% tariff reduction on all imports) are much deeper. It is likely that competition from cheaper imports is huge, as shown by a 5.5% fall in production in manufacturing sector (Table 10), 5% fall in textile production, and 18.7% fall in beverages production. Some poor households may gain from the price fall, especially if the share of these imports in the consumption basket of the poor is large enough. However, for the poor employed in the manufacturing, textile, and beverages sectors, their wages decline as we shall see later in Table 11. They may become worse off as a result unless the cost of the consumption bundle falls more than their wages.

Domestic prices of sugar, livestock/livestock products, fish, cereals, and other food commodities went up due to increase in exports and domestic demand. For all these products, except fish, domestic production also went up. Domestic price of sugar increases by 1% (Table 10), in contrast with 15% price increase in the previous simulation (Table 6). Sugar production increases by 0.8 per cent (Table 10) under the current 100% tariff reduction on all imports as opposed to EAC tariff reduction (Table 6), which resulted in 3.5% increase in sugar production.

Note: /1 and 2 Table 5

The results presented in this table are derived from simulating a 100% reduction in import tariffs (except for tariffs on sensitive products). Original tariffs on sensitive sectors...
are maintained, since we expect these sectors to be excluded from future liberalization commitments, including that under EPA arrangement.

The poor rely very much on their labour, and thus defines their condition after a shock. In Table 11, we observe increase in demand for unskilled labour (in both rural and urban areas) and fall in demand for skilled labour in primary agriculture sectors (cereals, other food production sector, and livestock). As expected, sector wages for unskilled labour employed in the livestock sector, cereals, sugar and other food sectors improve (and the poor, by assumption gain). These sectors use more unskilled labour than the manufacturing and beverages sectors, which have seen their production contract after the shock and, as expected, manufactured wages drop and skilled sector wages fall in primary sectors. The rise in unskilled sector wages and fall in skilled wages can be seen as reflecting a narrowing of the wage gap between skilled and skilled workers.

In Zimbabwe, Chitiga et al. (2005) find similar increase in wages for unskilled workers employed in the primary agriculture sector in the magnitude of 10.4% and a corresponding 11.4% fall in skilled wages. Hertel et al. (2003)’s findings for Uganda on factor incomes also show an increase in average earnings for land, labour and capital, and of course increased demand for these factors under multilateral liberalization.

</table>

Note: /1 as in Table 5

Based on these results, it may then be expected that the poor in rural areas benefit from 100% reduction in tariffs because demand for their labour increase, stepping up their wages while at the same time seeing the prices of the goods they produce go up.

The poor who are employed primarily in the exportable sector and consume importable goods gain more from full liberalization than those who are primarily employed in the import-competing sector, and consume primarily exportable goods. In the long run, as labour and capital become mobile across sectors, labour should pay across sectors. We would also expect to see the import sector contract in relative terms, while the exports sector expands and domestic industries are able to adjust.
Analyzing revenue impact (Simulations 1-3)

As already discussed before, our model ensures revenue neutrality; any reduction in government revenue from tariff cuts is compensated endogenously by additional VAT and income tax. However, we are also interested in the revenue impact of tariff reduction. By relaxing the neutrality assumption, changing some closure rules and re-running simulations 1-3 (that is a 100% tariffs reduction on EAC imports, a 100% reduction on COMESA tariffs, and a 100 per cent reduction of tariffs on all imports from EAC, COMESA and ROW, including sensitive products), we obtain results reported in Table 12.

Revenue falls by 13.2 per cent after simulation 1, by 8 per cent after simulation 2, and by 19.6 per cent after simulation 3 (Table 12). These results suggest that Uganda’s trade liberalization in the context of EAC/COMESA integration (i.e., a complete phase out of intra-EAC or intra-COMESA tariffs) or in a multilateral context (i.e., removal of tariffs on imports from EAC, COMESA and ROW) will lead to revenue losses. Multilateral liberalization will account for most of the revenue losses.

</tbody>
</table>

Note: /3/ coffee, tea, tobacco, cotton/textile, vanilla, cocoa, flowers

As we saw in Table 4, about 70% of total tariffs revenue in 2007 was collected on imports from ROW (trading partners outside EAC and COMESA). Across sectors, tax revenue declines in all sectors. As can be observed, most of the revenue losses are from manufactured imports: over 15% of potential revenue from manufactured imports is lost due to EAC tariffs reform, 11% due to liberalizing COMESA imports, and 43% due to multilateral liberalization.

Uganda’s reliance on tariff revenues remains high (above 21% of total tax revenues). Without wide bases for consumption and income taxes to compensate for the decline in tariff revenues, multilateral liberalization has the potential to stifle government expenditure: government demand for commodities, payment of wages and capital and
delivery of public goods, including expenditure on poverty reduction programmes and transfers (pension).

**Poverty impact of the tariff reductions (Simulations 1-3)**

The results in Table 13 demonstrate the effect of simulating three shocks, viz: removal of EAC tariffs, removal of non-EAC COMESA tariffs, and removal of all tariffs. We observe that monetary poverty line decreases in all cases, but it falls more in the case of a complete removal of tariffs (by 2.94%), than in the case of removal of EAC tariffs (2.76%), or removal of non-EAC COMESA tariffs (1.08%).

Note: */1 NHS: monetary poverty line published in the Uganda National Household Survey 2002/2003; /2 monetary poverty line (Base) generated by the model is much the same with food poverty line in 1/; Household Survey (the poverty line allows for some limited expenditure on non-food items that constitute the basic needs; 3/poverty line generated by the model within 10-15% change in elasticity parameters.

The fall in poverty line in each of these cases is induced by a combination of factors, including a fall in composite prices of commodities comprising the basic needs basket of the poor. The decrease in composite prices is attributed to a fall in relative prices of imports (in domestic currency) following a removal of tariffs.

The results suggest that all the three liberalization strategies (removing EAC tariffs, non-EAC COMESA tariffs, and all tariffs) are likely to facilitate poverty reduction in Uganda. However, greater poverty reduction is likely to be achieved with across-the-board tariffs reduction (i.e., removing tariffs on all imports from EAC, COMESA and ROW).

We explore this further by applying the Foster, Greer and Thorbecke (1984) (FGTα) decomposable indices (P0 and P1). Analysis centres on changes in indices after the shocks. Table 14 shows the changes in poverty headcount index (the proportion of people living below the poverty line, and the poverty gap index (the depth of poverty, the minimum cost of eliminating poverty through perfectly targeted transfers).
National poverty headcount (including poverty in rural and urban areas) falls in all cases (removal of EAC tariffs, removal of non-EAC COMESA tariffs, and removal of all tariffs), but it falls more in the case of a complete removal of tariffs by 3.2%, and least in the case of removal of non-EAC COMESA tariffs (1.3%). These results reinforce the findings on Table 13, which shows the potential poverty (reduction) impact of fully liberalizing trade as opposed to regional trading arrangement.

</table>

Table 14 further indicates that poverty headcount index falls more in urban areas than in rural areas, in all the cases. For example, poverty headcount falls by 3.4% in urban areas after removal of all tariffs (simulation 3) against a 2% fall in rural areas.

The depth of poverty (as measured by poverty gap index, $P_1$) has gone down in all the cases, and in both urban and rural areas. Like the case of headcount index, poverty gap index shows more improvement in the case of removal of all tariffs (where it declined by 3.1%) than the case of removal of EAC or non-EAC COMESA tariffs (simulations 1 and 2, respectively). $P_1$ falls more in urban areas than in rural areas; for example, a 3.5% fall in urban poverty gap compared with a 1.9% fall in rural poverty gap after a removal of all tariffs (simulation 3, Table 14). The results suggest that the cost of lifting the poor (all households below the poverty line) out of poverty through transfers will be lower under multilateral trade liberalization than under regional integration (removal of tariffs on EAC or non-EAC COMESA tariffs).

The severity of poverty, measured by $P_2$, falls in all cases; by 4% with removal of EAC tariffs, 2% with removal of non-COMESA EAC tariffs, and by 6% with removal of all tariffs. Severity of poverty falls more in urban areas than in rural areas.

**Sensitivity analysis**

The simulation results are influenced by the choice of parameters in the model. This section highlights the impact (on the results) of varying the values of some
of the key parameters. There are three parameters that have had a strong impact on the results: the elasticities of substitution between imports of different origin; elasticities of substitution between domestic and imported goods; and elasticities of transformation (in CET function). All parameters retained their standard (original) values, except the parameter in question. Variables associated with welfare improvements, for example domestic output, and wages reacted positively to an increase in substitution elasticities. This is not surprising, since higher elasticities imply that agents are able to shift to sectors, products and sources that are cheaper and economically more rewarding.

By varying the elasticity estimates (from about 10 to 50 percentage point below and above the standards GTAP elasticity indexes), the poverty line index varied between -0.01 to about -1.2 percentage points in the three simulations, and the effects were much stronger for the third policy scenario (100% reduction in tariffs) than any of the two simulations performed separately.
6. Conclusions and policy implications

In this paper, we have outlined the developments in trade policies in Uganda since the 1980s and have provided empirical evidence on how tariffs reduction can impact on poverty. Evidence from a CGE evaluation of trade policies at regional level (EAC and COMESA) reveals differences in impact of these policies on key macro variables and poverty level. However, it shows that both of them will be poverty reducing. A complete phase out of tariffs on EAC imports is likely to reduce poverty, as shown in the decrease in poverty threshold (-2.76%) and poverty headcount index. Tariff reduction on COMESA imports is also likely to facilitate poverty reduction (as poverty line decreased by 1.08% on implementing this policy, poverty headcount decreased in rural and urban areas). Still, we can conclude that greater poverty reduction is likely to be achieved with liberalization that is wider in scope than free trade arrangement under EAC and COMESA alone (as evidenced by 2.94% fall in poverty threshold with wider tariff reduction). However, noting the reaction to tariff reduction of the sectors that are currently classified as ‘sensitive’ in Uganda, care is needed when opening up these sectors to free trade due to vulnerability from increased imports.

One of the most influential channels of trade policy in Uganda is the first order effect transmitted through the price of imports. This implies that policy to reduce poverty need to pay more attention to enhancing output in import-competing sectors, and stimulating production and exports in the agricultural sector. This will minimize the long run price effects of rising imports when these sectors are fully open to competition.
Notes

1. A household that appears not to be poor according to the standard national poverty line could actually be poor if a poverty line based on the (high) cost of living in her region were used instead (Okurut et al., 2002).

2. Many argue that, at the time when the CMB was a monopoly in coffee export, farmers’ share of the export price was less than 30%. This share rose to 82% in 1996/97 from 45% in 1991/92 (as unit export price for Uganda coffee increased 3-fold from US$ 0.82/kg in 1992 to US$ 2.55/kg in 1994/95) following liberalization of the coffee sector in 1991. But how do we attribute this to the policy change?

3. Furthermore, a protocol establishing a common market for EAC was signed on 19th November 2009, coming into effect on 1st July 2010. It is expected to facilitate movement of persons, labour, and services within the EAC, as well as a right to establishment and residence of EAC citizens within the community. This in turn is expected to increase intra-EAC trade and help facilitate poverty reduction.

5. Annex I to the EAC Customs Union Protocol.

7. Category “A” goods from EAC partner states enter into each others’ territory free of customs duty.

8. They are Burundi, Comoros, DR Congo, Djibouti, Egypt, Eritrea, Ethiopia, Kenya, Libya, Madagascar, Malawi, Mauritius, Rwanda, Seychelles, Sudan, Swaziland, Uganda, Zambia, and Zimbabwe.

9. They are Burundi, Comoros, Djibouti, Egypt, Kenya, Libya, Madagascar, Malawi, Mauritius, Rwanda, Sudan, Zambia and Zimbabwe.

10. Some modellers have used income deciles to group the households; others have used socio, demographic, or geographic criteria.

11. The LES utility function restricts households to consuming a basket of subsistence goods. The minimum consumption of a good by one household is derived using the
Frisch parameter and the income elasticity. For a detailed presentation, see Dervis et al. (1982).

12. That is, \( P_\alpha = \frac{1}{n^*} \sum_{i=1}^{q} \left( \frac{z - y_i}{z} \right)^\alpha \)

where \( y_i \) is adult equivalent consumption expenditures for those individuals below the poverty line, and zero for those above, \( z \) is the endogenous poverty line, \( n^* \) the total population, and \( q \) the number of poor people. The parameter \( \alpha \) takes the value of zero for the headcount index \( (P_0) \), 1 for the poverty gap \( (P_1) \) and 2 for the squared poverty gap \( (P_2) \).

1: EAC common external tariff 6
Abstract

This paper examines the impact of trade liberalization on poverty in Uganda. Using a Computable General Equilibrium (CGE) framework and benchmark data from the 2002 household survey, three simulations are performed: removal of EAC tariffs, removal of non-EAC COMESA tariffs, and removal of all tariffs. Results indicate that poverty falls in all cases, but poverty falls much more in the case of a complete removal of tariffs on all imports (2.94%), compared with the case of removal of EAC tariffs (2.76%) or non-EAC COMESA tariffs (1.08%).
